

A Observe every baseline excursion and its linked reward

Retain both excursions: $Y_1 > 0$ and $Y_2 = 0$. Zero linked seconds is an observed outcome.

B Estimate

Baseline excursions and rewards

$$a_0(d, z) = \mathbb{E}(Y \mid D = d, Z = z)$$

Duration alone, or features
with stated coarsening

C Replay

Candidate-limit excursions
on the same observed trace

$$\nu_{u_1}(dd, dz)$$

Frequency and composition

D Standardise

Candidate linked alarm burden

$$B_m(u_1) = \int a_0 d\nu_{u_1}$$

Compare with the baseline limit

estimated reward

Interpretation and uncertainty State reward transport and overlap; report coarsening and unlinked burden. Resample patients to quantify uncertainty in the cell-standardised comparison.
